See related article www.cmaj.ca/lookup/doi/10.1503/cmaj.170431

Chronic noncancer pain includes any painful condition that persists for at least three months and is not associated with malignant disease.¹ According to seven national surveys conducted between 1994 and 2008, 15%–19% of Canadian adults live with chronic noncancer pain.² Chronic noncancer pain interferes with activities of daily living, has a major negative impact on quality of life and physical function,³ and is the leading cause of health resource utilization and disability among working-age adults.^{4,5}

In North America, clinicians commonly prescribe opioids for acute pain, palliative care (in particular, for patients with cancer) and chronic noncancer pain. Canada has the second highest rate per capita of opioid prescribing in the world when measured using defined daily doses, and the highest when defined using morphine equivalents dispensed, with more than 800 morphine equivalents per capita in 2011.^{6,7}

Substantial risks accompany the use of opioids in chronic noncancer pain. In Ontario, admissions to publicly funded treatment programs for opioid-related problems doubled from 2004 to 2013, from 8799 to 18 232.^{8,9} Among Ontarians receiving social assistance, 1 of every 550 patients started on chronic opioid therapy died of opioid-related causes at a median of 2.6 years from the first opioid prescription, while 1 in 32 of those receiving 200 mg morphine equivalents daily (MED) or more died of opioid-related causes.¹⁰ An estimated 2000 Canadians died from opioid-related poisonings in 2015¹¹ and initial numbers for 2016 are higher, with most deaths attributed to fentanyl.¹²

In 2010, the National Opioid Use Guideline Group offered recommendations for safe and effective use of opioids.¹³ Many of the recommendations were nonspecific and almost all supported the prescribing of opioids; the guideline provided few suggestions about when not to prescribe.¹¹ A time-series analysis in Ontario, Canada, from 2003 to 2014, found a slight decline in overall opioid

KEY POINTS

- We recommend optimization of nonopioid pharmacotherapy and nonpharmacologic therapy, rather than a trial of opioids, for patients with chronic noncancer pain.
- Patients with chronic noncancer pain may be offered a trial of opioids only after they have been optimized on nonopioid therapy, including nondrug measures.
- We suggest avoiding opioid therapy for patients with a history of substance use disorder (including alcohol) or active mental illness, and opioid therapy should be avoided in cases of active substance use disorder.
- For patients beginning opioid therapy, we recommend restricting to less than 90 mg morphine equivalents daily (MED) and suggest restricting the maximum prescribed dose to less than 50 mg MED.
- Patients already receiving high-dose opioid therapy (≥ 90 mg MED) should be encouraged to embark on a gradual dose taper, and multidisciplinary support should be offered where available to those who experience challenges.

prescribing, but no change in rates of fatal opioid overdose and increases in both high-dose opioid prescribing and opioid-related hospital visits. Moreover, 40% of recipients of long-acting opioids received > 200 mg MED, and 20% received > 400 mg MED.¹⁴

This updated guideline incorporates all new evidence published subsequent to the literature search that was used to inform the 2010 guideline. It adheres to standards for trustworthy guidelines¹⁵ and aspires to promote evidence-based prescribing of opioids for chronic noncancer pain. The full guideline is available in Appendix 1 (at www.cmaj.ca/lookup/suppl/doi:10.1503/cmaj.170363/-/DC1) and at <http://nationalpaincentre.mcmaster.ca/guidelines.html>.

Scope

The purpose of this clinical practice guideline is to inform the prescribing of opioids for adults with chronic noncancer pain. The target audience includes those who prescribe opioids or create policy regarding this issue. This guideline does not address the management of acute or subacute pain, care at the end of life or treatment of opioid addiction or opioid use disorder.

Methods

In developing this guideline, the steering committee followed standards for trustworthy guidelines.¹⁵ We included innovative approaches for key standards such as patient involvement, panel and committee composition, and competing interest management. We performed systematic reviews and applied the Grading of Recommendations Assessment, Development and Evaluation (GRADE) system to meet standards of evidence assessment and recommendation development.^{16,17} For complete details on our methods, see Appendix 1 and www.magicapp.org/public/guideline/8nyb0E.

Health Canada and a grant from the Canadian Institutes of Health Research provided funding for this guideline.

Guideline development group

The development of our guideline was supported by four groups: a steering committee, guideline panel, clinical expert committee and patient advisory committee. The four-member steering committee (GHG, JWB, DNJ and DNB) oversaw all aspects of guideline development. Additionally, an evidence synthesis team conducted the systematic reviews and other literature searches.

The guideline panel consisted of 13 clinicians (most with extensive methodological training; one is a medical regulator) and two patient representatives. Most panel members had no financial or intellectual conflicts of interest (see competing interest statements at end of article and at <http://nationalpaincentre.mcmaster.ca/guidelines.html>). The panel had extensive input into the development and presentation of the recommendations, voted on all recommendations and is ultimately responsible for the recommendations and their presentation.

To ensure that the guideline development was informed by the necessary expertise in management of chronic pain and use of opioids, the steering committee enlisted 13 experienced clinicians to serve on a clinical expert committee. These individuals were not voting panel members and were not present when the recommendations were developed. The clinical expert committee comprised experts with a range of views on the role of opioids in the management of chronic pain, including those who viewed opioids as having an important role and others who viewed the practice of using opioids in this setting with extreme skepticism. This committee informed the selection of guideline recommendation topics, provided clinical practice guidance in areas where evidence was absent or limited, and reviewed the final guideline.

To optimize patient involvement in our guideline, the steering committee included two patient representatives on our guideline panel and created a 16-member patient advisory committee of patients from across Canada with a variety of opinions regarding the use of opioids in the management of chronic pain. Fourteen

patients were living with chronic pain and used (or had used) prescription opioids, one had experience with opioid addiction and another represented a family member who had fatally overdosed on prescription opioids. The patient advisory committee approved the outcomes constituting the focus of the systematic reviews that summarized the evidence for our recommendations, and informed our values and preferences statement.

Guideline development

Research questions

The evidence synthesis team reviewed the 2010 Canadian Guideline for Safe and Effective use of Opioids for Chronic Non-Cancer Pain,¹³ as well as six other recently published guidelines addressing the use of opioids for chronic noncancer pain,^{18–22,53} and summarized all prior recommendations. The steering committee held a national stakeholder meeting on July 17, 2015, to discuss previous recommendations and identify other relevant topics for recommendations. Attendees included representatives from law enforcement, pharmacy, medical regulation, patient advocacy groups, family medicine, pain medicine, addiction medicine, coroners, nursing, Workers' Compensation Boards, the Canadian Centre on Substance Abuse, the Canadian Agency for Drugs and Technologies in Health (CADTH) and Health Canada.

Systematic reviews

The evidence synthesis team conducted systematic reviews using standardized forms in an online data abstraction program (DistillerSR, Evidence Partners, Ottawa, Canada; <https://systematic-review.ca>) to inform our recommendations. The team searched for evidence in AMED, CINAHL, Cochrane Library, Embase, MEDLINE, PsycINFO, and PubMed through October 2016, including randomized trials and observational studies (excluding case reports). The guideline panel and the evidence synthesis team interacted regularly to ensure harmonization of the scope, approach and output of the systematic reviews, and development of the recommendations. The evidence synthesis team created evidence summaries using the GRADE system to provide a clear description of benefits and harms, along with a rating of the certainty of the evidence on an outcome-by-outcome basis (Box 1).

Reviewers from the evidence synthesis team assessed the risk of bias from randomized trials using a modified Cochrane risk of bias instrument,²³ and from observational studies using criteria from the *Users' Guides to the Medical Literature*,²⁴ including representativeness of the study population, validity of exposure and outcome assessment, loss to follow-up and whether predictive models were optimally adjusted.

Values and preferences

To complement the research findings and to guide the guideline panel's recommendations, the steering committee developed a values and preferences statement. This statement was informed by a systematic review of the literature of patient values and preferences for opioid therapy, and through discussions with the patient advisory committee (Appendix 2, available at www.cmaj.ca/lookup/suppl/doi:10.1503/cmaj.170363/-/DC1).

Development of recommendations

The guideline includes three categories of guidance: recommendations (supported by evidence from randomized controlled trials or observational studies), good practice statements (supported by indirect evidence), and expert guidance (supported by little or no published evidence).

We applied the GRADE system to move from evidence to recommendations.^{25,26} Our guideline panel and clinical expert committee attended an in-person meeting on Jan. 5, 2017, as did representatives from Health Canada. The primary purpose was to discuss issues for which there was no — or very limited — research evidence in order to develop clinical expert guidance. These included restrictions with respect to the quantity of opioids prescribed, use of immediate- versus controlled-release opioids, coprescribing of sedatives, management of opioid-induced sleep apnea or hypogonadism, and strategies for mitigating risk (i.e., treatment agreements, urine drug screening, tamper-resistant formulations, fentanyl patch exchange and coprescribing of naloxone).

Box 1: How to use and understand this guideline

This guideline provides prescribers and patients with a basis for decisions about using opioids to manage chronic noncancer pain. Prescribers, patients and other stakeholders — particularly regulatory agencies or the courts — should not view the recommendations in this guideline as absolute. No guideline can account for the unique features of patients and their clinical circumstances; this guideline is not meant to replace clinical judgment.

Statements about qualifying remarks and values and preferences are integral parts of the recommendations and are meant to facilitate accurate interpretation of the guideline. These should never be omitted when quoting or translating recommendations from this guideline. Recommendations in this guideline are categorized according to the Grading of Recommendations Assessment, Development and Evaluation (GRADE) system as strong or weak recommendations.¹⁵⁻¹⁷

Strong recommendations indicate that all or almost all fully informed patients would choose the recommended course of action, and indicate to clinicians that the recommendation is appropriate for all or almost all individuals. Strong recommendations represent candidates for quality of care criteria or performance indicators.

Weak recommendations indicate that the majority of informed patients would choose the suggested course of action, but an appreciable minority would not. With weak recommendations, clinicians should recognize that different choices will be appropriate for individual patients, and they should help patients arrive at a decision consistent with their values and preferences. Weak recommendations should not be used as a basis for standards of practice (other than to mandate shared decision-making).

The guideline also contains best practice statements and clinical expert guidance, which are distinct from recommendations that have been formally categorized using GRADE. Good practice statements represent common-sense practice, are supported by indirect evidence, and are associated with assumed large net benefit. Clinical expert guidance provides direction in areas for which there is either no published evidence or insufficient evidence to justify a formal recommendation. These do not have the force of either recommendations that have been categorized using GRADE or good practice statements.

Members of the guideline panel, along with two Health Canada observers, attended a second in-person meeting on Jan. 6, 2017. Panellists reviewed relevant evidence for each recommendation and used anonymous, online voting software (<https://ietd.epistemionikos.org>) to select their recommendation: strong in favour, weak in favour, weak against, or strong against. We required endorsement by 80% of panel members for acceptance of a recommendation.

The guideline panel also endorsed three good practice statements intended to offer actionable guidance for interventions with compelling indirect evidence of large net benefits (www.magicapp.org/goto/guideline/8nyb0E/section/jmA7Mj).²⁷ Input from medical regulators (the College of Physicians and Surgeons of Ontario, College of Physicians and Surgeons of British Columbia, College of Physicians & Surgeons of Nova Scotia and Federation of Medical Regulatory Authorities of Canada) guided our selection of good practice statements.

External review

We posted the draft guideline recommendations on the National Pain Centre website (<http://nationalpaincentre.mcmaster.ca/>) for public consultation, from Jan. 30 to Feb. 28, 2017. We encouraged participation by inviting 429 stakeholders by email and announced the opportunity for review through a national press release and on social media.

The steering committee reviewed and summarized more than 500 comments, which it carefully considered when drafting the final guideline. Neither the direction nor strength of any recommendations changed because of feedback; however, the steering committee did make wording changes and added details to clarify areas of concern. Finally, the draft guideline was reviewed by an external review committee for adherence to the “Clinical Practice Guidelines We Can Trust” checklist from the Health and Medicine Division, National Academies of Sciences, Engineering, and Medicine (www.nationalacademies.org/hmd/Reports/2011/Clinical-Practice-Guidelines-We-Can-Trust.aspx).

Guideline format

We partnered with the Making GRADE the Irresistible Choice (MAGIC) nonprofit initiative to optimize presentation of the guidelines, in digitally structured and multilayered formats available on all devices, and to develop decision aids for clinicians to use in shared decision-making.²⁸

Recommendations

We developed 10 recommendations, 7 of which focus on harm reduction. Box 2 and multilayered formats in MAGICapp (www.magicapp.org/public/guideline/8nyb0E) provide our 10 recommendations and associated remarks. Here we describe five key recommendations in greater detail.

Maximizing nonopioid treatment

When considering therapy for patients with chronic noncancer pain, we recommend optimization of nonopioid pharmacotherapy and nonpharmacologic therapy, rather than a trial of opioids (strong recommendation). See www.magicapp.org/goto/guideline/8nyb0E/rec/LqQP6L for details.

Rationale

When added to nonopioids, opioids may achieve, on average, modest improvements in pain and function relative to other pain treatments at the cost of a small but important risk of nonfatal and fatal unintentional overdose, very frequent physical dependence and frequent addiction (Supplementary Tables 3a–e in Appendix 3, avail-

able at www.cmaj.ca/lookup/suppl/doi:10.1503/cmaj.170363/-/DC1). As first-line treatment for patients with chronic noncancer pain, several nonopioid therapies may achieve a similar degree of improvement in pain and function (e.g., nonsteroidal anti-inflammatory drugs [NSAIDs], graduated exercise, cognitive behavioural therapy), but without the harms of dependence, addiction and overdose.

Box 2: Summary of recommendations for opioid therapy and chronic noncancer pain*

Recommendation 1: When considering therapy for patients with chronic noncancer pain, we recommend optimization of nonopioid pharmacotherapy and nonpharmacologic therapy, rather than a trial of opioids (strong recommendation) (www.magicapp.org/goto/guideline/8nyb0E/rec/LqqP6L).

Recommendation 2: For patients with chronic noncancer pain, without current or past substance use disorder and without other active psychiatric disorders, who have persistent problematic pain despite optimized nonopioid therapy, we suggest adding a trial of opioids rather than continued therapy without opioids (weak recommendation) (www.magicapp.org/goto/guideline/8nyb0E/rec/j91boj).

- By a trial of opioids, we mean initiation, titration and monitoring of response, with discontinuation of opioids if important improvement in pain or function is not achieved. The studies that identified substance use disorder as a risk factor for adverse outcomes characterized the conditions as alcohol abuse and dependence, and narcotic abuse and dependence, and sometimes referred to International Classification of Diseases, 9th revision (ICD-9) diagnoses. The mental illnesses identified in studies as risk factors for adverse outcomes were generally anxiety and depression, including ICD-9 definitions, as well as “psychiatric diagnosis,” “mood disorder” and post-traumatic stress disorder.

Recommendation 3: For patients with chronic noncancer pain with an active substance use disorder, we recommend against the use of opioids (strong recommendation) (www.magicapp.org/goto/guideline/8nyb0E/rec/jxZ7Dn).

- Clinicians should facilitate treatment of the underlying substance use disorders, if not yet addressed. The studies that identified substance use disorder as a risk factor for adverse outcomes characterized the conditions as alcohol abuse and dependence, narcotic abuse and dependence, and sometimes referred to ICD-9 diagnoses.

Recommendation 4: For patients with chronic noncancer pain with an active psychiatric disorder whose nonopioid therapy has been optimized, and who have persistent problematic pain, we suggest stabilizing the psychiatric disorder before a trial of opioids is considered (weak recommendation) (www.magicapp.org/goto/guideline/8nyb0E/rec/jzPK1n).

Recommendation 5: For patients with chronic noncancer pain with a history of substance use disorder, whose nonopioid therapy has been optimized, and who have persistent problematic pain, we suggest continuing nonopioid therapy rather than a trial of opioids (weak recommendation) (www.magicapp.org/goto/guideline/8nyb0E/rec/j79BGn).

- The studies that identified a history of substance use disorder as a risk factor for adverse outcomes characterized the conditions as alcohol abuse and dependence, and narcotic abuse and dependence, and sometimes referred to ICD-9 diagnoses.

Recommendation 6: For patients with chronic noncancer pain who are beginning opioid therapy, we recommend restricting the prescribed dose to less than 90 mg morphine equivalents daily, rather than having no upper limit or a higher limit on dosing (strong recommendation) (www.magicapp.org/goto/guideline/8nyb0E/rec/jmJ0VL).

- Some patients may gain important benefit at a dose of more than 90 mg morphine equivalents daily. Referral to a colleague for a second opinion regarding the possibility of increasing the dose to more than 90 mg morphine equivalents daily may therefore be warranted in some individuals.

Recommendation 7: For patients with chronic noncancer pain who are beginning opioid therapy, we suggest restricting the prescribed dose to less than 50 mg morphine equivalents daily (weak recommendation) (www.magicapp.org/goto/guideline/8nyb0E/rec/noAgMj).

- The weak recommendation to restrict the prescribed dose to less than 50 mg morphine equivalents daily acknowledges that there are likely to be some patients who would be ready to accept the increased risks associated with a dose higher than 50 mg in order to potentially achieve improved pain control.

Recommendation 8: For patients with chronic noncancer pain who are currently using opioids, and have persistent problematic pain and/or problematic adverse effects, we suggest rotation to other opioids rather than keeping the opioid the same (weak recommendation) (www.magicapp.org/goto/guideline/8nyb0E/rec/nJM4bL).

- Rotation in such patients may be done in parallel with, and as a way of facilitating, dose reduction.

Recommendation 9: For patients with chronic noncancer pain who are currently using 90 mg morphine equivalents of opioids per day or more, we suggest tapering opioids to the lowest effective dose, potentially including discontinuation, rather than making no change in opioid therapy (weak recommendation) (www.magicapp.org/goto/guideline/8nyb0E/rec/L4BypE).

- Some patients may have a substantial increase in pain or decrease in function that persists for more than one month after a small dose reduction; tapering may be paused or potentially abandoned in such patients.

Recommendation 10: For patients with chronic noncancer pain who are using opioids and experiencing serious challenges in tapering, we recommend a formal multidisciplinary program (strong recommendation) (www.magicapp.org/goto/guideline/8nyb0E/rec/ERX6WL).

- In recognition of the cost of formal multidisciplinary opioid reduction programs and their current limited availability/capacity, an alternative is a coordinated multidisciplinary collaboration that includes several health professionals whom physicians can access according to their availability (possibilities include, but are not limited to, a primary care physician, a nurse, a pharmacist, a physical therapist, a chiropractor, a kinesiologist, an occupational therapist, an addiction medicine specialist, a psychiatrist and a psychologist).

*Available at www.magicapp.org/public/guideline/8nyb0E.

CADTH has compiled the evidence supporting nonopioid therapies for chronic noncancer pain (www.cadth.ca/evidence-bundles/opioid-evidence-bundle/browse-category#alternatives).

Evidence summary

We found low-quality evidence that opioids may have similar effects on pain relief as NSAIDs, tricyclic antidepressants, or nabilone (a synthetic cannabinoid), and similar improvements in physical function as NSAIDs, anticonvulsants, tricyclic antidepressants or nabilone (Supplementary Tables 3a–e, Appendix 3). High-quality evidence shows that opioids increase the rate of gastrointestinal adverse events compared with NSAIDs, and low-quality evidence shows that they may increase the rate of gastrointestinal adverse events compared with anticonvulsants and tricyclic antidepressants (Supplementary Tables 3a–e, Appendix 3).

Trial of opioids

For patients with chronic noncancer pain, without current or past substance use disorder and without other active psychiatric disorders, who have persistent problematic pain despite optimized non-opioid therapy, we suggest adding a trial of opioids rather than continued therapy without opioids (weak recommendation). See www.magicapp.org/goto/guideline/8nyb0E/rec/j91boj for details.

By a trial of opioids, we mean initiation, titration and monitoring of response, with discontinuation of opioids if important improvement in pain or function is not achieved. A reasonable trial of therapy should be accomplished within three to six months; opioids provide less pain relief after three months and some patients may continue use to address inter-dose withdrawal symptoms.

The studies that identified substance use disorder as a risk factor for adverse outcomes characterized the conditions as alcohol abuse and dependence, and narcotic abuse and dependence, and sometimes referred to International Classification of Diseases, 9th revision (ICD-9) diagnoses. Moderate-quality evidence did not support an association between smoking status and opioid misuse (adjusted odds ratio [OR] 1.29, 95% confidence interval [CI] 0.97–1.7).^{29–32} The mental illnesses identified in the studies as risk factors for adverse outcomes were most typically anxiety and depression, including use of ICD-9 definitions, as well as “psychiatric diagnosis,” “mood disorder” and post-traumatic stress disorder.

Rationale

When added to nonopioids, opioids achieve, on average, modest improvements in pain and function. Adverse effects include relatively frequent constipation, nausea and vomiting, sedation and addiction, and a small but important risk of unintentional overdose, which can be fatal. The risk of unintentional overdose increases progressively with the daily dose prescribed (Supplementary Table 3f, Appendix 3).

Evidence summary

We found moderate-quality evidence that opioid add-on therapy versus no opioid add-on therapy has, on average, a modest effect on pain reduction (best estimate of percentage of patients achieving a reduction in pain greater than the minimally important difference is 11.1%), and on functional improvement (best estimate for achieving an important improvement in function is 10.0%), but also

increases the risk of gastrointestinal adverse events, including vomiting, nausea and constipation (5.8% more gastrointestinal adverse events) (Supplementary Table 3f, Appendix 3).

Chronic opioid therapy (treatment for more than three months) is associated with a 5.5% risk of addiction and, at very low doses (< 20 MED/day), a 0.2% risk of nonfatal overdose and a 0.1% risk of fatal overdose; the risk of overdose increases at higher doses (Supplementary Table 3f, Appendix 3). In 2013, 4.9% of Americans admitted to nonmedical use of prescription opioids.³³ Data from population surveys suggest similar rates among Canadian adults.³⁴

Dosing

For patients with chronic noncancer pain who are beginning opioid therapy, we recommend restricting the prescribed dose to less than 90 mg MED, rather than having no upper limit or a higher limit on dosing (strong recommendation). We suggest restricting the prescribed dose to less than 50 mg MED (weak recommendation). See www.magicapp.org/goto/guideline/8nyb0E/rec/jmJ0VL and www.magicapp.org/goto/guideline/8nyb0E/rec/noAgMj for details.

The weak recommendation to restrict the prescribed dose to less than 50 mg MED acknowledges that some patients will be willing to accept the increased risks associated with doses exceeding 50 mg in order to potentially achieve improved pain control. Further, some patients may gain important benefit at a dose of more than 90 mg. Referral to a colleague (not necessarily a pain specialist) for a second opinion regarding the possibility of increasing the dose to more than 90 mg MED may therefore be warranted in some individuals.

Rationale

Observational studies provide moderate-quality evidence of a progressive increase in the likelihood of unintentional nonfatal overdose or death as the prescribed dose of opioids increases. These serious outcomes are very uncommon in patients prescribed less than 50 mg MED, but increase in those prescribed doses of 50 mg to 90 mg, and although still uncommon, are further increased in those prescribed doses of more than 90 mg MED.

Evidence summary

Meta-regression of within-trial comparisons of different doses of opioids found moderate-quality evidence against a dose–response effect for pain relief ($p = 0.49$) or functional recovery ($p = 0.22$).^{35–40} However, there is likely a dose-dependent increase in the risk of nonfatal opioid overdose: 0.2% for < 20 mg MED/day; 0.7% for 50–99 mg MED/day; and 1.8% for ≥ 100 mg MED/day.⁴¹ Moreover, there is an increased risk of fatal opioid overdose with higher doses: 0.1% for < 20 mg MED/day; 0.14% for 20–49 mg MED/day; 0.18% for 50–99 mg MED/day; and 0.23% for ≥ 100 mg MED/day.¹⁰

Tapering

For patients with chronic noncancer pain who are currently using 90 mg MED per day or more, we suggest tapering opioids to the lowest effective dose, potentially including discontinuation, rather than making no change in opioid therapy (weak recommendation). See www.magicapp.org/goto/guideline/8nyb0E/rec/L4BypE for details.

Some patients are likely to have a substantial increase in pain or decrease in function that persists for more than one month after a small dose reduction; tapering may be paused and potentially abandoned in such patients.

Rationale

Reduction in opioid dose may reduce adverse effects, including cognitive impairment and the likelihood of nonfatal or fatal unintentional overdose. If not done gradually, dose reduction may cause increased pain, decreased function or highly aversive symptoms of opioid withdrawal.

Evidence summary

We found low-quality evidence that tapering may eventually result in a substantial reduction in opioid dose, or cessation of opioids altogether. This may reduce the risk of opioid-related harms, although it is uncertain whether tapering has an effect on pain (Table 1).

Implementation

We have made strong recommendations to optimize nonopioid therapy (including nondrug therapies) before considering a trial of opioids, and to refer patients struggling to reduce their opioid dose for multidisciplinary care. Both recommendations are subject to resource availability: physicians cannot be required to deliver services that are unavailable. Rather, policy-makers should explore opportunities to facilitate access to evidence-based therapies for patients with chronic noncancer pain.

Canadian physicians' awareness of and adherence to the 2010 Canadian guideline recommendations for use of opioids to manage chronic pain have been limited.⁴⁴ We have formally explored barriers to implementation⁴⁵ and used the findings (e.g., excessive length of guidelines) to guide design and format of the current guideline. Clinicians can facilitate shared decision-making using consultation decision aids available through the MAGIC applica-

Table 1: The effect of opioid tapering versus maintaining the dose for adult patients with chronic noncancer pain using 90 mg morphine equivalents of opioids per day or more*

Outcome follow-up	No. of studies	Absolute effect estimates	Quality of evidence	Plain language summary
Pain (11-point NRS; lower is better)† 6–12 mo	2 studies (73 patients) ^{42,43}	In one study, ⁴² pain was reduced on an 11-point NRS from mean (SD) of 8.00 (0.30) at baseline to 3.35 (0.33) at 6 mo. In the other study, ⁴³ 40% of patients reported less pain, 28% reported no change and 33% reported more pain after tapering	Very low, due to serious risk of bias‡ and serious imprecision§	We are uncertain about the effect of tapering on pain
Success of tapering 6–12 mo	2 studies (73 patients) ^{42,43}	In one study, ⁴² 100% of patients successfully tapered opioids. In the other study, ⁴³ 47 of 50 (94%) of patients successfully tapered opioids	Low, due to serious indirectness¶ and serious imprecision§	Success of tapering may be high in this patient population

Note: NRS = Numeric Pain Rating Scale, SD = standard deviation.
 *Available at www.magicapp.org/SoF9.
 †Minimally important difference for pain on an 11-point NRS is a reduction of 2 points.
 ‡Neither study enrolled a comparison group.
 §Small number of patients.
 ¶These 2 studies defined "success of tapering" differently. Baron and McDonald⁴² enrolled patients into a voluntary inpatient detoxification program intended to taper them off prescription opioids if the patient or physician felt that the patient was not getting benefit from high doses of opioids. No patient was referred for diversion, overuse, abuse or addition to opioids. The goal of the program was to taper patients completely off opioids. Harden and colleagues⁴³ included individuals drawn from a list of patients initiated on an opioid taper at a US Veterans Affairs medical centre. A taper was considered successful if the patient's dose at 12 months was less than the baseline dose.

Table 2: Conversion ratios for opioids

Opioids*	To convert to oral morphine equivalent, multiply by:	To convert from oral morphine, multiply by:	50 mg morphine equivalent dose, mg/d	90 mg morphine equivalent dose, mg/d
Codeine	0.1–0.2	6.67	334	600
Hydromorphone	5.0	0.2	10	18
Morphine	1.0	1.0	50	90
Oxycodone	1.5	0.667	33	60
Tapentadol	0.3–0.4	3.33	160	300
Tramadol	0.1–0.2	6.0	300	540†

*Conversion ratios for opioids are subject to variations in kinetics governed by genetics and other drugs.
 †The maximum recommended daily dose of tramadol is 300 mg to 400 mg, depending on the formulation.
 Source: Modified from Nielsen and colleagues.⁵²

tion.⁴⁶ We are seeking funds to support the development, delivery and measurement of a national knowledge translation strategy.

The National Pain Centre (<http://nationalpaincentre.mcmaster.ca/>) aims to provide an ongoing review of new evidence by dynamically updating recommendations as needed, yielding a “living guideline.”⁴⁶ Having all the content digitally structured and published in MAGICapp facilitates dynamic updating from a technical perspective; however, updating of guidelines requires resources for which the centre is seeking funds. If we are unable to implement the dynamic updating process, we plan to update this guideline (at minimum) within five years of publication (estimated 2022).

Other guidelines

Several guidelines for prescribing of opioids for chronic pain have been published in the last five years (Appendix 4, available at www.cmaj.ca/lookup/suppl/doi:10.1503/cmaj.170363/-/DC1); however, only the 2016 United States Centers for Disease Control and Prevention (CDC) guideline⁴⁷ has been endorsed by selected provincial colleges of physicians and surgeons^{48,49} in Canada. Our recommendations regarding dose escalation for patients initiating opioid therapy are consistent with the CDC guideline. Limitations of the CDC guideline include the heavy involvement of experts critical of opioid use for chronic noncancer pain, limited involvement of patients, excessive restrictions on the selection of evidence, suboptimal application of the GRADE rating system, excessive use of strong recommendations in the face of low-quality evidence and vagueness in some recommendations.⁵⁰ The current guideline addresses these limitations.

Gaps in knowledge

Clinical trials of opioids for chronic noncancer pain failed to follow patients for more than one year, enrolled limited patient populations and did not provide a comprehensive assessment of outcomes. None of the instruments designed for screening patients for high risk of adverse outcomes with opiate use have been shown to predict patients unsuitable for opioid therapy,⁵¹ and no risk mitigation strategy has convincingly shown reduced harm for patients prescribed opioid therapy. Research addressing these issues would be valuable.

Conclusion

The limited evidence base for opioid therapy for chronic noncancer pain supports offering a trial of opioids to selected patients with chronic noncancer pain who have not found sufficient relief with optimized nonopioid therapy (see Table 2 for opioid conversions).⁵² The harms associated with opioid therapy are substantial; indeed, 7 of our 10 recommendations focus on harm prevention. Although the evidence supports dose limits for patients beginning opioid therapy, those currently receiving high-dose opioid therapy constitute a distinct population, and tapering efforts should be individualized and should consider patients' values and preferences.

Competing interests: D. Norm Buckley and Jason Busse report grants from Health Canada during the conduct of the study. Jason Busse received grants from the Canadian Institutes of Health Research (CIHR) during the conduct of the study. D. Norm Buckley reports grants from Purdue Pharma and Janssen Inc. outside the submitted work. Chris Cull received personal fees from Indivior. David Juurlink reports grants from CIHR and from the Ontario Ministry of Health and Long-Term Care, and personal fees outside the submitted work. Sol Stern was a member of advisory boards for Astra Zeneca, Bristol-Myers Squibb and Johnson and Johnson; received fees for expert opinions from the Canadian Medical Protective Association; received consulting fees from mdBriefCase.com, Ethypharm and Sea Courses; and received honoraria for Continuing Medical Education presentations from Purdue Pharma and Paladin. No other competing interests were declared.

Contributors: All of the authors contributed substantially to the interpretation of the findings and to writing the article. All of the authors gave final approval of the version to be published and agreed to act as guarantors of the work. Participation in the clinical expert committee or patient advisory committee in no way constitutes endorsement of guideline recommendations.

Funding: This guideline was an investigator-initiated study, supported by grants from the Canadian Institutes of Health Research and Health Canada. Health Canada personnel provided non-binding feedback during the preparation of the guideline. The funders had no other role in the design or conduct of the study; collection, analysis and interpretation of the data; or preparation, review or approval of the guideline. Final decisions regarding the protocol and issues that arose during the guideline development process were solely the responsibility of the guideline steering committee.

Disclaimer: Nav Persaud is an associate editor for *CMAJ* and was not involved in the editorial decision-making process for this article.

Guideline steering committee: Gordon H. Guyatt (Chair), D. Norm Buckley, Jason W. Busse, David N. Juurlink

Guideline panel members: Jason W. Busse (Chair), Thomas Agoritsas, Elie A. Akl, Alonso Carrasco-Labra, Lynn Cooper, Chris Cull, Bruno R. da Costa, Joseph W. Frank, Gus Grant, Gordon H. Guyatt, Alfonso Iorio, Navindra Persaud, Sol Stern, Peter Tugwell, Per Olav Vandvik

Clinical expert committee: D. Norm Buckley, Donna Buna, Gary Franklin, Chris Giorshv, Jeff Harris, Lydia Hatcher, Kurt Hegmann, Roman Jovey, David N. Juurlink, Priya Manjoo, Pat Morley-Forster, Dwight Moulin, Mark Sullivan

Patient advisory committee:* Bart Bennett, Lynn Cooper, Chris Cull, Ada Giudice-Tompson, Deborah Ironbow, Pamela Jessen, Mechelle Kane, Andrew Koster, Sue Mace, Tracy L. Mercer, Kyle Neilsen, Ian Tregunna, Jen Watson. *Three members did not provide written consent to be listed.
